## **Keck NGAO**

#### Systems Engineering Status

2007 Mar 07

**Richard Dekany** 

Associate Director for Instrumentation Caltech Optical Observatories

## Systems Engineering Status

- Overview
  - Performance Budgets
  - Trade Studies
  - System Architecture
- Updates from Performance Budget Teams

## Performance Budgets

- Overall ~50% complete
  - Good progress on
    - Refining WFE budget & high-contrast budget tools
    - Identifying photometric, astrometric, and polarimetric drivers
      - Some IPT's investigating limiting factors using real Keck data (not yet understood)
      - Will have to draw a line and write these reports 'as are'
    - Understanding current limits to observing efficiency / uptime
  - Need to improve
    - Documentation efficiency
      - Only draft report to date: photometric precision
    - Some progress being limited by inter-project dependencies
      - E.g. Not having definitive observing scenarios, instrument requirements, etc.

## Trade Studies

- Overall ~30% complete
- Good progress on
  - Digging into difficult technical issues
  - Collecting and understanding previous analyses
  - Teamwork
- Need to improve
  - Setting priorities
    - Spirit of the SD phase was to pass through *all* major issues (as understood in Aug 2006) in a timely fashion to identify the major drivers
      - Then, based on a preliminary architecture downselect, revisit the important issues in more detail
      - Iterate with the science team
    - Several TS's have gone 3x their budgeted scope
  - Documentation efficiency
    - More report drafts; more comments

## System Architecture

- Initial ideas being explored in several activities ٠ 3.1.1 Performance Budget - update today (R. Dekany) ٠ MOAO V. MCAO - update today (D. Gavel) 3.1.2.1.1 ٠ NGAO vs. Keck Upgrades 3.1.2.1.2 - update today (P. Wizinowich) • 3.1.2.1.3 AM2 • 3.1.2.1.4 K & L Band Science • 3.1.2.1.5 Keck Interferometer Support - update today (C. Neyman) ٠ 3.1.2.1.6 Instrument Balance • 3.1.2.1.7 GLAO for non-NGAO - update today (R. Flicker) • 3.1.2.1.8 Instrument Reuse • 3.1.2.2.2 Optical Relay - update today (B. Bauman) • 3.1.2.2.3 Field Rotation Strategy - update today (B. Bauman) ٠ ٠
  - Synthesis methodology pending WBS 3.1.3 Work Scope Planning Sheet (R. Dekany)
    - Goal is adoption of NGAO Baseline Architecture at July 2007 NGAO retreat

#### Wavefront Error and Ensquared Energy IPT Status

Richard Dekany (IPT Lead) Don Gavel, Ralf Flicker, Claire Max, Peter Wizinowich

#### Wavefront Error Budget

Topic	<u>Worksheet</u> <u>Name</u>	<u>in puts</u>	<u>Outputs</u>	<u>To Do</u>	Comments
In put Summary	Input Summary	This sheet collects the major system parameters for several AO systems and manufacture scenarios	Many outputs are linked to the Optimization worksheet		
Optimization	Optim	Results weilengths Results weilengths WFSIntegration times TT guide star search radius LGS asterism radius	RMS WFS Streh I ratio TT errors Sk y coverage Assumptions and parameters Publishable summary table	Add MCAO blind mode error terms to spreadsheet Add TT multspectral error Add generalized anisoptanatism to handle MCAO architectures	
Telescope	Tel	Telescope name (some values are picked up from this) Telescope diameter Obscuration dameter (equivalent circular obscuration) Focal ratio Static aberration information Dynamic aberration information	Uncorrectable static errors Uncorrectable dynamic errors	Check Keck equivalent circular obscuration value For uncorrectable telescope errors, the number of available actuators is currently being drawn from the HO-Flux page, but this link isn't obvious - should probably separate num acts (Hitling?) and num subtaps (HO Flux)	
Atmosphere	Aim	Or*2(h) model Wind model r0 Turbulence-weighted wind Outer scale Atmospheric pressure model Atmospheric exfinction model Zenith angle of observation	ThetaO ThetaO (finite aperture) Greenwood frequency tau0 Till tacking frequency d0 (Hardy) d0 (KACN 208) Scintilation index Effective turbulence height Global one-axis tilt Peak tilt	Currently atmospheric extinction is monochromatic, based on UKIRT data - update to have specifal information from various sites (if available) Obtain better(?) estimates of outer scale from various sites (at least document source of assumed values).	
High order WFS Flux	HO Rux	Guide star type (NGS/LGS) Subaperture geometry (square/circ) Subaperture width Integration time Apparent mag of GS (mV) Choice of spectral bands Transmission model QE model	Subaperture area Photodetections per subap per exposure Shotnoise	Add ADC transmission losses where appropriate (should this be per AO system mode or by Closer Mng scenario?)	
LGS Return Rux	LGS Flux	Laser power Laser pulse format Transmission model Silope efficiencies Na density Measured vs. Theoretical return estimates	Transmitted power Na layer distance Delivered power Na return flux per subap per exposure time	Need to include saturation effects in the theoretical photoreturn estimates for different pulse formats	
High order Centroiding Error	HO Cent	Sensing wavelength Pixel sampling per subap Intrinsic SG dameter LGS beam aberrations Uplink correction ? Rayleigh gating? Off-axis launch distance Sensor type (SH/Pyr) Downlink residual aberrations Charge diffusion CCD read noise model Sky back ground flux Dark current model Rayleigh scatter model	Total number of pixels per measurement Max LGS elongation Mean LGS elongation Delivered Na spot size WFS optical spot size Subapdificaction Spot size for centroiding SNR of detection RMS centroid error	Verify values in Rayleigh scatter model Consider the impact on PSF shape arising from DMsaturation (the effect is not simply to scatter light our of the core) Need to include SNR reaction due to fratricide in CVM multi-laser scenario - start with single value global degradation (modal analysis will have to come from all-in simulations.) Add the dingation' option to model tracking of short-pulse lasers (with or without uplink AC) Add techniques for handling other centrolding algorithms (e.g. matched filters), not just the Hardy 5.14 implementation	
High order Measurement Error	HO Meas	Error propagator model (Hardy)	Estimate of measurement error		
Focal Anisoplanatism / Tomograph y Error	FA Tomog	Number of LGS beacons LGS height at zenith Model of Tomograph yerror based on simulations Special case of small quincunx? (Yes/No)	Estimate of focal anisoplanatism error for 1 LGS beacon, or tornography error for multiple beacons	Update tomograph y error using Raifs latest values Only valid beam height currently is 90km - need to make dependent upon zenith angle Small quincunx case is probatly now superceded by more detailed results	
Asterism Deformation Error	Ast Def	Vertical velocitymodel for the Earth's sodium layer	Physical focus shift P-V mm of focus shift PMS till difference between u plink and down beams Estimate of wavefront error due to asterism deformation		
Sodium Layer Height Focus Error	Na H	Model of focus correction factor coming from LOWFS or Slow WFS	Estimate of error due to un predictable Na layer height	Make LOWFS or Slow WFS distinct options	
Fitting Error	Fit	Atting error coefficient, aF	Approximate total number of actuators Estimate of fitting error	See To Do item under 'Tel' work sheet Note, multiple LGS can in theory better sample the atmosphere than the 'dassical' fitting error - consider dividing into sampling error and DM fitting error	

#### Improvements tracked using 'punch list'

(about 30 implemented since 1/16/07)

Major items:

Observing scenarios Improved Rayleigh contamination model Measured LGS return Better SNR model through servo loop Benefit of single-laser tomography Separate transmission models for Keck AO and Keck NGAO (LGS & NGS) Truth WFS now has own bandwidth Total WFE now calc directly from HO+TT Strehl

#### Latest NGAO wavefront error estimates

Science	Guide Star	HO Err	TT Err	Total Err	N_subap_	Dond	Strehl

- Many parameters set by observing scenario
  - Zenith angle
  - Guide star brightness and color
  - Required sky coverage
- Global Assumptions:
  - Median  $r_0 = 18$  cm
    - Turbulence-weighted wind speed = 8 m/s
    - CN N2 C<sub>n</sub><sup>2</sup>(h) model
    - 50 m outer scale

- Sodium laser guide star FWHM = 1.47 arcsec
  - 150 W CW w/ measured SOR return
  - 4 x 10<sup>9</sup> atoms/cm<sup>2</sup> abundance
  - Transmission to WFS ~23%
  - Single laser tomography FA reduction = 0.8
- Vis HOWFS
  - CCID56
    - 2.4 e- read noise (max; varies)
    - 4 x 4 pixels per subaperture
    - 6.4 arcsec diam field stop
    - Optimize for N<sub>subaps</sub>
    - Optimize for t<sub>integration</sub>

- IR TT sensors (x2) + IR TTFA (x1)
  - Distinction of TTFA v. TT not made
  - H2RG
    - MOAO compensated IR guide stars
    - 4.5e- IR read noise (fixed)
  - 2 x 2 pixels per subaperture
  - 0.1 x 0.1 arcsec field stop
  - Measured NIRC2 thermal background
  - ADC in sensor
  - Optimize for off-axis TT guide star distance
- Vis TWFS sensor
  - CCD39

# SEE PRESENTED FOR BUILDER BOUCHEZ

Antonin Bouchez (IPT Lead) Brian Bauman, Richard Dekany

## Photometric Precision IPT Status

Matthew Britton (IPT Lead) Richard Dekany, Ralf Flicker, Knut Olsen

### **Photometric Precision**

- Matthew Britton posted v0.2 of the IPT technical report
  - February 15, 2007
    - 22 pages contains technical descriptions of key drivers
  - Awaiting comments from the IPT, including details from L. Olsen
  - Excellent collection of references
    - PSF estimation
    - PSF reconstruction and star-finding codes
- Concise numerical tool for rapid re-evaluation of quantitative precision budget proving elusive
  - Likely to rely on systems engineering team understanding content of this report

#### Astrometric Accuracy IPT Status

Brian Cameron (IPT Lead) Matthew Britton, Richard Dekany, Andrea Ghez, Jessica Lu

#### **Astrometric Accuracy**

- Brian Cameron at Keck this week
  - Working on distortion solutions and NIRC2 characterization with Keck staff
- · Jessica Lu, et al., cranking away on Gal Cen data
  - Rank order of limitations to astrometric accuracy not yet settled
  - No obvious NGAO design drivers yet identified except:
    - Better Strehl and Strehl stability are good in crowded fields
    - The most sensitive TT sensors probably allow most flexibility for crafting strategies that minimize tip/tilt anisoplanatism over moderate FoV's
  - Will remain research area for periods long relative to SD Phase
- Concise numerical tool for rapid re-evaluation of quantitative precision budget proving elusive
  - Likely to rely on systems engineering team understanding content of the astrometric accuracy technical report

## High-Contrast IPT Status

#### Ralf Flicker (IPT Lead) Richard Dekany, Mike Liu, Bruce Macintosh, Chris Neyman

## **Companion Sensitivity**

- IPT members: R. Dekany, R. Flicker (lead), M. Liu, B. Macintosh, C. Neyman
- Status of work:
  - Have initial performance budget spread sheet tool
  - Still needs improvement in a few areas
    - segment aberration/vibration PSD's, LGS specific errors, coronagraph details
  - Draft report in embryonic state
    - · most of the mathematical analysis, some technical description, written up
    - science & observing scenarios, method description, results (etc) yet to be written

	Speckle time	PSF intensity	Photon noise	Long-exposure	Post-SSDI	SSDI
	(sec)	Normalized peak	=1	speckle noise	speckle noise	factor

Total speckle+photon fina				2.30E-05		

Sample (typical) contrast performance budget

### Polarimetric Accuracy IPT Status

Mike Ireland (IPT Lead) Richard Dekany

#### **Polarimetric Accuracy Performance Budget**

- Key science metric is polarimetric accuracy as a function of distance from the PSF core
  - E.g. 10<sup>-4</sup> at 100 mas means the ability to detect a blob of dust 100 mas from a central source at 10-σ that scatters 1% of the incident radiation with 10% fractional polarization.
- Two different kinds of performance budgets, depending on polarimeter architecture
  - "Back-end" polarimeter
    - The entire polarimetry instrument is behind the entire NGAO system.
  - "Split" polarimeter
    - The polarization is modulated by an element (waveplate or variable retarder) downstream of only the primary, secondary and tertiary mirrors.

#### **Polarimetric Accuracy Performance Budget**

- "Back-end" polarimeter budget :
  - How does the differential wavefront between different polarization states translate to a difference in PSF between polarization states?
    - <u>Differential wavefront error</u> is due primarily to reflections off flat optics in converging beams and is mainly astigmatic.
    - With no (quasi-) static aberrations, a pure astigmatism differential aberration translates to zero PSF difference. The PSF difference is dominated by a cross-term that is linearly proportional to (quasi-) static aberrations and linearly proportional to the differential wavefront
      - E.g. 0.1 radians static astigmatism and 0.1 radians differential wavefront gives PSF difference which is 10<sup>-2</sup> of the diffraction-limited PSF: better than10<sup>-4</sup> at 2nd Airy ring or beyond. Math to come in report...
  - At what level can <u>an observer calibrate</u> the PSF difference using a standard star and how does this relate to quasi-static aberrations?
    - It is difficult (impossible?) to completely correct for static aberrations if a standard star is observed after a <u>K-mirror rotation or telescope elevation change</u>.
      - Obviously, quasi-static aberrations that change between observations can not be corrected.

#### • "Split" polarimeter budget:

- More complex
- Will only be examined if the "back-end" budget can not deliver adequate performance for primary science goals.
